StressLens

Work time. Voluntary check-ins. Clear reports.

I wanted a clearer way to keep track of work time and record how I felt during the day. StressLens brings that idea into a local Python/Streamlit prototype with a work clock, optional answers and descriptive charts.

Actual application capture from a disposable QA session, 20 October 2026. Camera-off controls and optional reminders; the clock value is outside this capture.

My contribution

I defined the use case, directed priorities, requested changes and reviewed the experience. Codex assisted with implementation, debugging, tests and documentation. This is a record of that collaborative work.

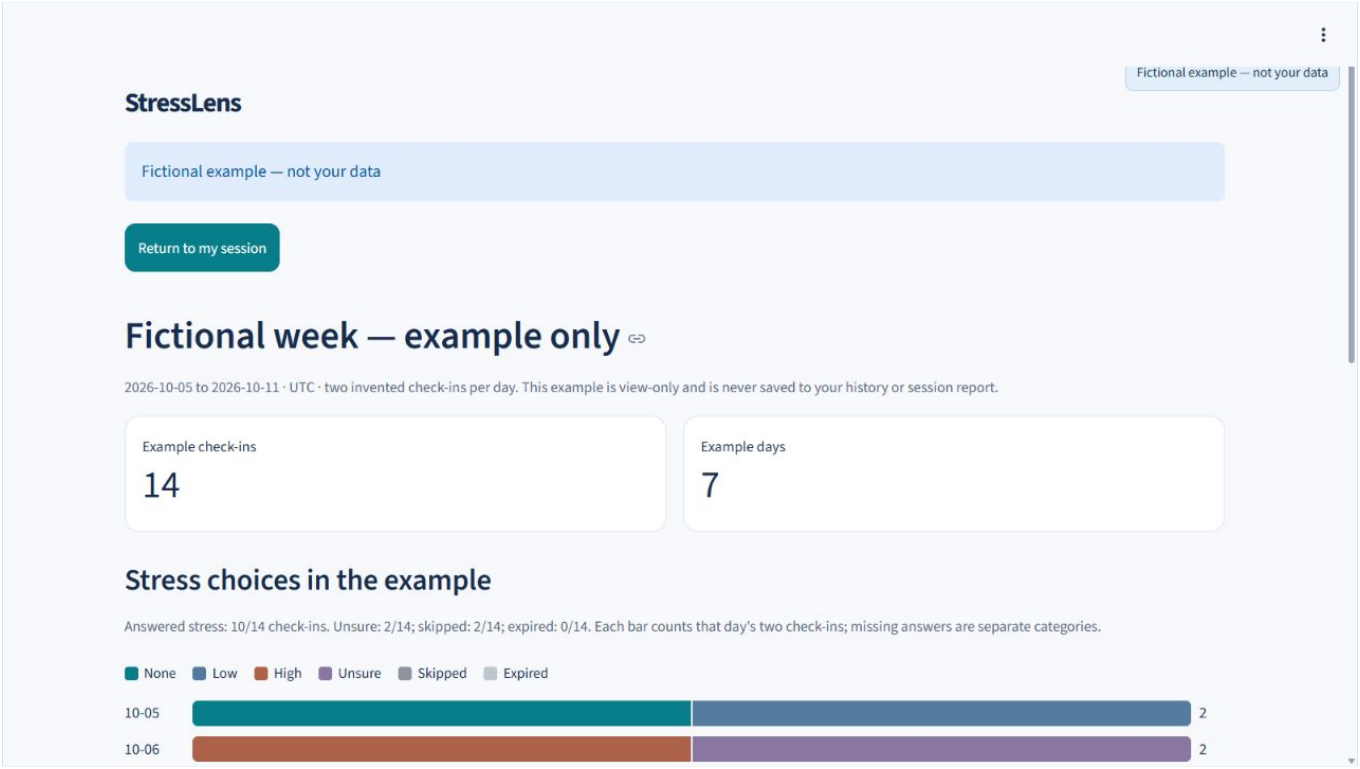

What the prototype includes

Explicit Start/Pause/Resume/End controls; voluntary check-ins; optional in-app reminders; descriptive category charts; and separate JSON/TXT session reports.

The core demonstration works with the camera off. The project does not establish stress from facial movement or diagnose a condition.

Make the data understandable

The design choices are visible in the product and traceable in the source. I focused the review on what a record means, what is missing and where an example belongs.

Fourteen invented check-ins across seven UTC days. The example is labelled and isolated from the personal session. It is not participant or adoption data.

01 Keep missing answers visible

An unsure or skipped answer is not a zero. Charts preserve these categories and show the denominator, so the reader can see what was and was not recorded.

02 Separate examples from personal records

The fictional week is view-only. Returning to the personal session must not insert the invented answers or change the work clock.

03 Preserve the source of each value

Self-reports, imported readings and optional camera observations remain distinct. JSON and TXT describe the same session report; the fictional-week view has no export.

Source and test pointers: docs/PORTFOLIO.md and docs/VERIFICATION.md in the project package.

What was checked

The accepted software checks are dated 20 October 2026. These results describe specific scopes, not scientific or production validation.

484

passing source tests

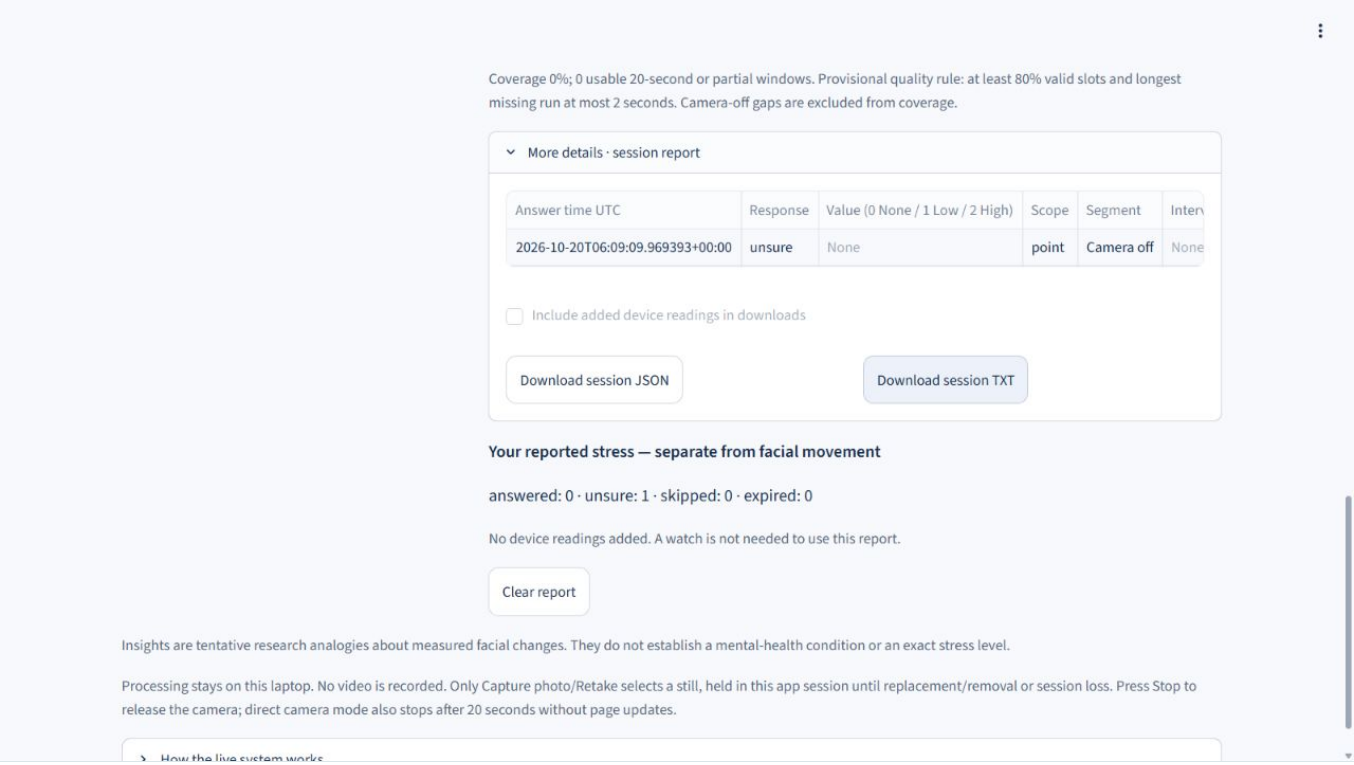

10 real-SDK skips; 7 subtests passed. Ruff clean.

208

passing package-core tests

Seven model-free test files; existing dependencies.

The two scopes overlap: do not add the counts. These are retained release results; the suites were not rerun for this document.

A fictional unsure answer has no numeric value. The separate session report offers JSON/TXT. Approved QA capture, 20 October 2026.

Checks beyond the unit suite

Disposable browser checks covered work controls, fictional-example isolation, report exports and Clear. A separate Codex review accepted the original 73-file archive. This presentation copy preserves all 63 frozen source/test/config/asset files.

Where the evidence stops

Physical-camera/SDK performance, clean-machine installation and scientific stress validation remain unverified. The optional camera-rate decline has no established cause. There is no production deployment or verified business-impact claim.
